11th November 2017

# Word Pair Similarity

- The problem of quantifying the similarity level between two words is known as the *Word Pair Similarity (WPS)* problem.

<b>Word1</b>	<b>Word2</b>	<b>Similarity score [0,50]</b>
car	automobile	50
cat	kitten	49
bakery	zebra	0
evening	walk	27
apartment	valley	14

Table: Some manually marked similarity estimates from the MEN-3000 dataset.

# Word Pair Similarity

WPS plays an important role in natural language processing and information retrieval such as

- Sentence pair similarity
- Document summarization
- Automatic thesauri generation
- Automatic retrieval of similar words
- Query expansion
- Automatic analogy solving

WPS for image/video similarity

As long as we are willing to “look” at images using text.

# Two Types of Similarities Between Words

Medin *et al.* '90

- 1 **Attributional Similarity:** similar words share high degree of attributes.
  - Car is similar to a truck because they share some attributes (tires, driving, engine, etc.).
  - Lion is similar to a tiger because they share some attributes (big cats, claws, sharp teeth).
  - Cat is similar to a dog because both are pets.
- 2 **Relational Similarity:** words can be connected with each other through different relations.
  - Bright is the *antonym* of dark.
  - Smoking *causes* cancer.

# Attributional vs Relational Similarity

Happy – Sad – Surprised

- Happy, sad and disgusted share a common *attribute* of being human expressions.
- However, happy and sad share an additional *relationship* of being antonyms.
- Therefore, similarity between happy and sad should be different from similarity between happy and surprised.
- We explicitly exploit such relational information for computation of similarity.

# Previous work

## Word Embeddings

### Basic Idea

Embed words as points in a (continuous) vector space. Learn embeddings so that similar words are represented by similar vectors.

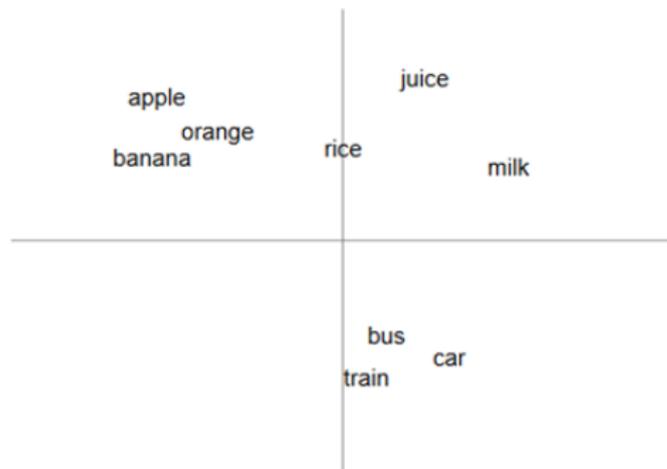

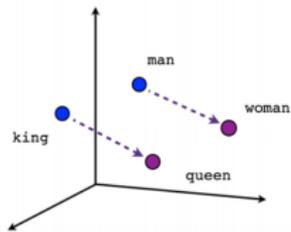

Figure: Groups of words which share similar meaning should be embedded in similar vector space locations. From [nlp.cs.tamu.edu/resources/wordvectors.ppt](http://nlp.cs.tamu.edu/resources/wordvectors.ppt).

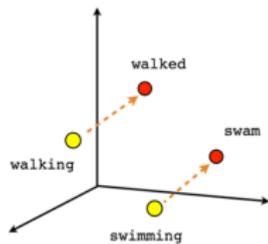

# Power of Word Embeddings

Word2Vec (Mikolov *et al.*), GLOVE (Pennington *et al.*)

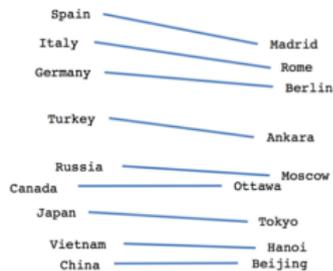

- They possess valuable information about words and their relations with each other.
- $\text{vector}[\text{Queen}] - \text{vector}[\text{King}] = \text{vector}[\text{Woman}] - \text{vector}[\text{Man}]$

Male-Female

Verb tense

Country-Capital

Figure: Embeddings should also reflect relationships between words.  
From [www.tensorflow.org/tutorials/word2vec](http://www.tensorflow.org/tutorials/word2vec).

# Well-known Word Embeddings

## **Learned from large text corpora**

- Word2Vec
- GLOVE

## **Learned from structured semantic networks**

- ConceptNet Numberbatch (CN16 and CN17)

# Visualization of Word Embeddings

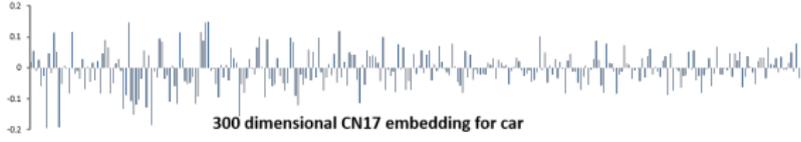

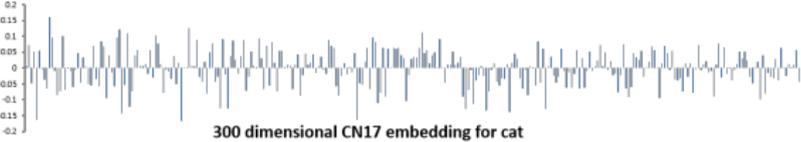

Car	 <p>300 dimensional CN17 embedding for car</p>
Automobile	 <p>300 dimensional CN17 embedding for automobile</p>
Cat	 <p>300 dimensional CN17 embedding for cat</p>

Table: Examples of Conceptnet Numberbatch word embeddings for car, automobile and cat. Cosine similarity between car and automobile embeddings is 0.8933. In contrast, embeddings of car and cat have similarity of only 0.1257.

# Current Approach

- 1 Embed individual words into a vector space.
- 2 WPS = cosine similarity of individual word vectors.

## Observations

Why stop at current embeddings?

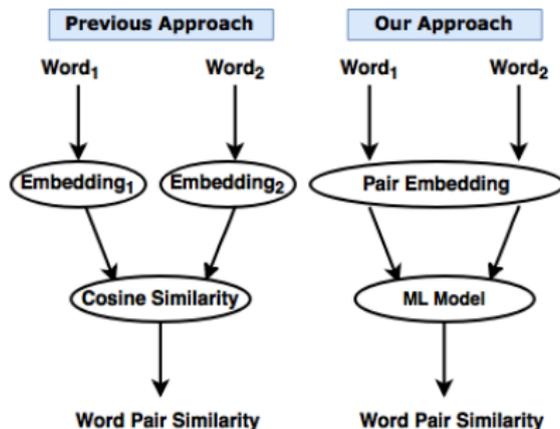

Why stop at cosine similarity?

# Alternatives

- 1  $e_1, e_2 \rightarrow \text{ML} \rightarrow \text{similarity value.}$
- 2  $e_{12} \rightarrow \text{ML} \rightarrow \text{similarity value.}$

Option 2 is advantageous because

- it can explicitly capture relational information between words, and
- size of embedding can be controlled (which implies that complexity of ML model can be controlled).

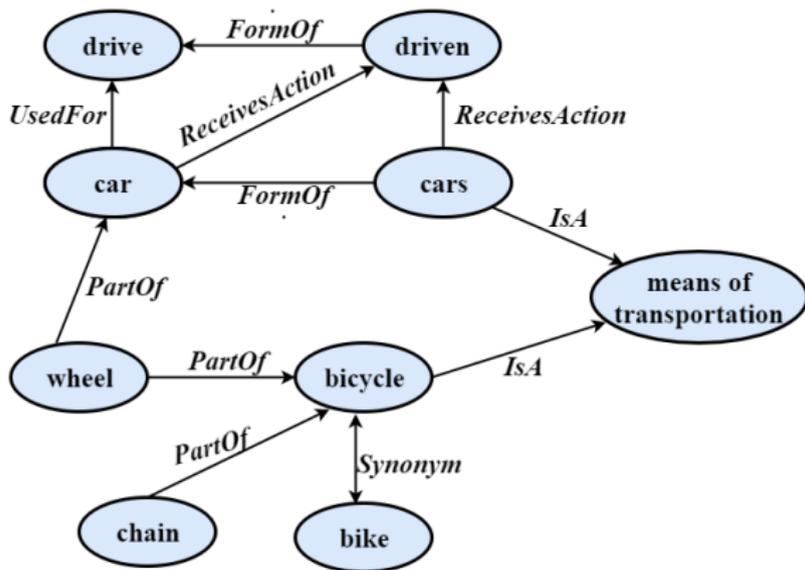

# Word Pair Embeddings

For word pair  $(w_1, w_2)$ , construct a 53 dimensional word pair embedding  $\mathbf{v}$

- The first element of  $\mathbf{v}$  is the dot-product of individual word embeddings.
- Last 52 elements of  $\mathbf{v}$  are relationship features extracted from ConceptNet.

# ConceptNet

A crowd-sourced semantic network of words and their relationships.  
Adapted from <https://blog.conceptnet.io/tag/conceptnet/>.

# ConceptNet

## Common sense knowledge in ConceptNet for the word "car".

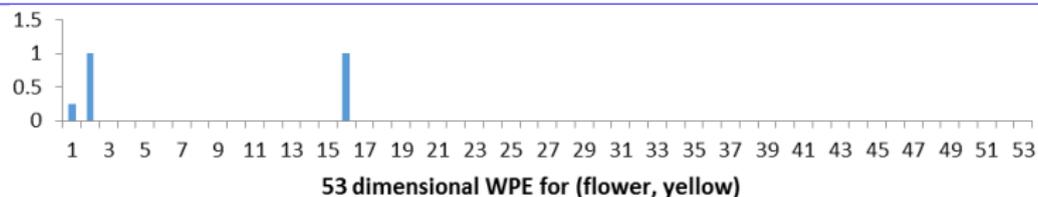

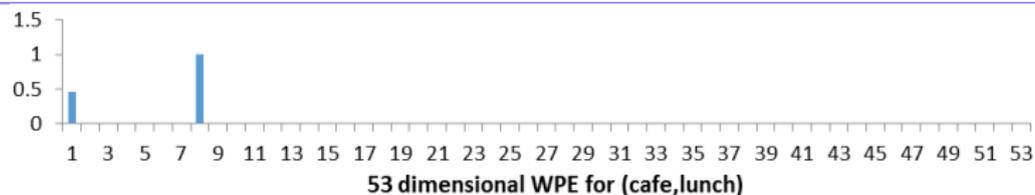

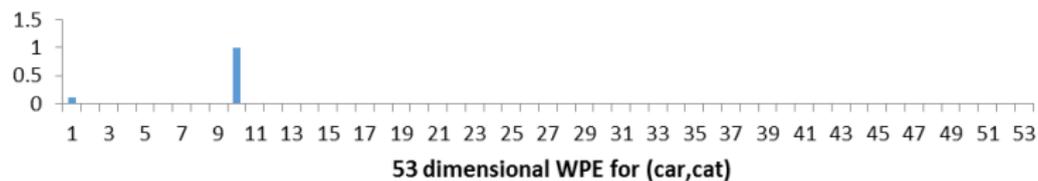

Related terms	Parts of car	Types of car	Synonyms

# Visualization of Word Pair Embeddings

# ML Models

- Our word pair embeddings can be used as inputs to any regression based machine learning model.
- Human marked similarity values can be used as targets for training.
- We use 2 simple models:
  - ① Regularized Linear Regression
    - Cross-validated the regularization hyperparameter in the range 0.001 to 1000.
  - ② Neural network with just 1 hidden layer containing only 3 neurons.
    - Bayesian regularization.

# Datasets

## ① MEN-3000

- A gold standard dataset with 3000 word pairs.
- All pairs with their crowd sourced similarity judgments.
- Comes with development (2000) and testing (1000) splits.
- Used to evaluate many WPS algorithms.

## ② WordSim-353

- 353 word pairs with their similarity judgments.
- Dataset does not come with development and testing splits.
- Similar to the MEN dataset, we picked every third word pair for testing.

# Results

## MEN Dataset

Embeddings	Model	Correlation
CN17	Cosine Similarity	0.8680
WPE(CN17)	Linear Regression	<b>0.8794</b>
WPE(CN17)	Neural Network	<b>0.8830</b>
CN16	Cosine Similarity	0.8612
WPE(CN16)	Linear Regression	<b>0.8736</b>
WPE(CN16)	Neural Network	<b>0.8794</b>
Glove42	Cosine Similarity	0.8143
WPE(Glove42)	Linear Regression	0.8109
WPE(Glove42)	Neural Network	<b>0.8538</b>

Table: Correlation between WPS predictions and ground-truth similarity estimates for MEN dataset using different embeddings and different models. CN17, CN16 and Glove42 are three different embeddings of individual words. WPE(X) denotes that embeddings from X were used to compute the cosine similarity feature only.

# Results

## WordSim-353 Dataset

Embeddings	Model	Correlation
CN17	Cosine Similarity	0.8385
WPE(CN17)	Linear Regression	<b>0.8524</b>
WPE(CN17)	Neural Network	<b>0.8435</b>
CN16	Cosine Similarity	0.8610
WPE(CN16)	Linear Regression	<b>0.8722</b>
WPE(CN16)	Neural Network	<b>0.8720</b>
Glove42	Cosine Similarity	0.8200
WPE(Glove42)	Linear Regression	0.7986
WPE(Glove42)	Neural Network	<b>0.8649</b>

Table: Correlation between WPS predictions and ground-truth similarity estimates for WordSim-353 dataset using different embeddings and different models. CN17, CN16 and Glove42 are three different embeddings of individual words. WPE(X) denotes that embeddings from X were used to compute the cosine similarity feature only.

# Conclusion

- State-of-the-art embeddings of individual words mainly capture attributional similarity.
- Pairs of words have relational similarity.
- Embeddings used for WPS should be computed at the level of word pairs.
- Results on the MEN and WordSim-353 datasets show that word pair embeddings are better than individual word embeddings for WPS computation.
